Note: Students are required to write the programs along with atleast two outputs for each experiment in the laboratory observation record. The observation record must be signed by the faculty in charge. For every laboratory session, the observation component carries **marks**.

1. **Swap Two Numbers**
   Write a Python program to read two numbers and swap their values without using a third variable. Display the values before and after swapping.
2. **Voting Eligibility**
   Write a Python program to read a person's age and determine whether the person is eligible to vote. If the age is negative, display an appropriate message.
3. **Extract Digits**
   Write a Python program to read a three-digit number and display its hundreds, tens, and units digits separately.
4. **Discount Calculation**
   Write a Python program to read the price of a product. If the price is ₹1000 or more, apply a 10% discount; otherwise, apply a 5% discount. Display the discount amount and the final price.
5. **Electricity Bill**
   Write a Python program to read the number of electricity units consumed and calculate the bill using the following tariff:

   First 100 units: ₹2 per unit

   Next 100 units: ₹3 per unit

   Above 200 units: ₹5 per unit

6. **Character Classification**
   Write a Python program to read a character and determine whether it is an uppercase letter, lowercase letter, digit, or special character.

7. **Divisibility Check**
   Write a Python program to read an integer and determine whether it is divisible by 3, divisible by 5, divisible by both 3 and 5, or divisible by neither.
8. **Sum of Digits**
   Write a Python program to read an integer and calculate the sum of its digits using a while loop.
9. **Numbers with a Condition**
   Write a Python program to read two integers representing a starting and ending value and display all numbers in that range that are divisible by 3 but not by 5.
10. **Value, Type and ID**
    Write a Python program to read a value from the user and display its value, data type using type(), and memory identity using id(). Then perform an arithmetic operation on the value and display the resulting value, data type, and ID.
